

NIFTY 50 Regime Dashboard - What I Did Today

An easy-words summary of today's work: switched to real market data, the accuracy jumped, and I built a full interactive dashboard (live on the office network). Last page compares today with yesterday.

1. In one line

I forecast the NIFTY 50 'market regime' (calm vs volatile, and bullish/bearish/sideways) for three time-frames - intraday, weekly expiry, monthly expiry - and put it all on a live dashboard.

2. The big win - real data made it much more accurate

Yesterday the intraday model used free internet data (only ~2 months). Today I used your REAL 1-minute NIFTY 50 data (2016-2026) and resampled it to 5-min and 15-min candles. Accuracy jumped:

Checked honestly: leak-free (a scramble test collapsed to random) and NOT overfit (train vs test gap of only 0.4%). So the jump is real, not luck.

3. The dashboard I built (live on the network)

- 4 model cards - Intraday 5m, Intraday 15m, Weekly, Monthly - each with its accuracy.
- Live forecast cards - the current call (trend + calm/volatile) for each time-frame.
- Market behaviour view - every day of 10 years marked bullish / bearish / sideways, with coloured candles.
- Yesterday's intraday chart - the latest full session, 09:15 to 13:15, candle by candle.
- Confidence curve + table - shows the confidence level above which the model is very accurate.
- Data tables - the last 50 predictions for each time-frame, with a clear 'take or skip' rule.

4. The models and their accuracy

Time-frame	What it predicts	Accuracy	Beats baseline by
Intraday 5m	calm / volatile (next 4h)	77.4%	+20.8
Intraday 15m	calm / volatile (next 4h)	75.8%	+18.9
Weekly	bull / bear / sideways (5d)	58.0%	+10.4
Monthly	calm / volatile (21d)	73.7%	+17.3

'Beats baseline' = how much better than a naive 'always guess the most common answer'.

5. Smart things on the dashboard

- **Confidence rule:** When the model is more CONFIDENT, it is right far more often. Example (intraday 5m): take only calls with confidence above 75% -> it is right 93% of the time.
- **Take / skip rule:** Only TAKE a call when confidence is 50% or more; below that it is a coin-flip, so SKIP it.
- **Validation:** Proved the regime is real - after a bullish day the market truly rises more than after a bearish day, at all three time-frames.
- **Market behaviour:** Each row also shows what the market ACTUALLY did (bullish/bearish/sideways) - very useful when a prediction misses.
- **Time fix:** Fixed the clock - intraday times now show correct IST (09:15), not UTC.

6. Market terms (easy)

Regime: The market's mood - calm vs volatile, or bullish / bearish / sideways.

Volatility: How much the price swings. Calm = small moves, Volatile = big moves.

Expiry: Option settlement - weekly = ~5 days, monthly = ~21 days.

Accuracy / Hit ratio: How often the prediction is correct.

Confidence: How sure the model is. We only act when it is at least 50% sure.

Candle: One bar of price (open, high, low, close) for a time period.

Honest testing: Train on the past, test on unseen future data - no cheating.

Today vs Yesterday

Yesterday I built and validated the models. Today I plugged in the real data and turned everything into a live, easy-to-read dashboard.

Side-by-side

Aspect	Yesterday	Today
Intraday data	internet, ~2 months	real 1-min, 10 years
Intraday accuracy	64.6%	77.4% / 75.8%
Intraday clock	wrong (UTC)	correct IST (09:15)
Dashboard	none	full, live on network
Market regime view	none	10 yrs, validated
Confidence guide	none	curve + table + rule
Take/skip rule	none	yes ($\geq 50\%$)
Sharing	GitHub only	live at 10.10.7.70:3000

Net result

- Intraday accuracy up +12.8 points - purely from using the real 1-minute data.
- From models-in-scripts -> a hosted, interactive dashboard anyone can open and read.
- Still fully honest: leak-tested, overfitting-checked, no peeking at the future.

Status: live and ready to present at <http://10.10.7.70:3000/our-models>
